I Git! Stashing Explained

by ABDULFATTAH POPOOLA on JUNE 5, 2014JUNE 7, 2014

Imagine these scenarios when working in Git:

1. You do not want to commit your unfinished work but need to switch to a new branch to start some new work immediately.
2. A git pull results in conflicts however you do not want to commit local changes yet.
3. You realize you have worked in the wrong branch and want to move your uncommitted work to the right branch.

The Git stash command would help in these situations – it takes all the changes in your working directory and puts them in a stack you can always access later.

The command does two things:

1. It saves the working directory and index to a safe temporary place (the latest stash is usually at `.git/refs/stash`).
2. Then, it restores the working directory and index to the most recent commit (i.e. the commit pointed to by HEAD).

Thus, you can go ahead and switch to a new branch or complete the pull after a stash.

```
1 | git stash
```

It might fail if you do not have any commit in the repository. You need to have at least a single revision as shown below:

```
1 | git init
2 | git stash
3 | //fatal: Bad revision 'HEAD'
4 | //fatal: Bad revision 'HEAD'
5 | //fatal: Needed a single revision
6 | //You do not have the initial commit yet
```

```

1 | echo "Temp" > temp
2 | git add temp
3 | git commit -m "stash first commit"
4 | git stash
5 | //No local changes to save

```

Next, lets stash some temporary changes; note that stashing does not save changes that are being tracked (more on tracking vs staging areas in an upcoming post insha Allaah).

```

1 | echo "staging" >> temp
2 |
3 | #Add changes to staging area
4 | git add temp
5 | git status
6 | #Should show staged changes to temp
7 |
8 | echo "tracking" > tracking
9 | git status
10 | #shows staged and tracked changes
11 |
12 | git stash
13 | #Saved working directory and index state
14 | #WIP on master: 2038ddd stash
15 |
16 | git status
17 | #clean staging area
18 | #Tracked changes unmodified

```

Using stashed work

The stash is a stack and can contain multiple changes. The following commands show how to interact with it.

```

1 | #list all stashed changes
2 | git stash list
3 |
4 | #apply the topmost stashed changes
5 | git stash apply
6 |
7 | #Show applied changes
8 | git status
9 |
10 | #Stash still has applied stash
11 | git stash list
12 |
13 | #Pop the stashed change at ref 2
14 | git stash pop stash@{2}
15 |
16 | #Show applied changes
17 | git status
18 |
19 | #Verify stash@{2} was removed
20 | git stash list
21 |
22 | #delete stash at ref 3
23 | git stash drop stash@{3}
24 |
25 | #Delete all stash entries
26 | git stash clear

```

The difference between apply and pop is simple: apply is non-destructive, it preserves the stashed entry on the stack while pop will remove it. The pop command can be seen as an *apply* + *drop* combo. And yes, it is possible to create a new branch from a stashed entry.

```
1 | # create a new branch from stash
2 | git stash branch newBranchForStash
```

It automatically checks out the branch too; but make sure the branch name is unique!

Done! Happy Stashing!!
